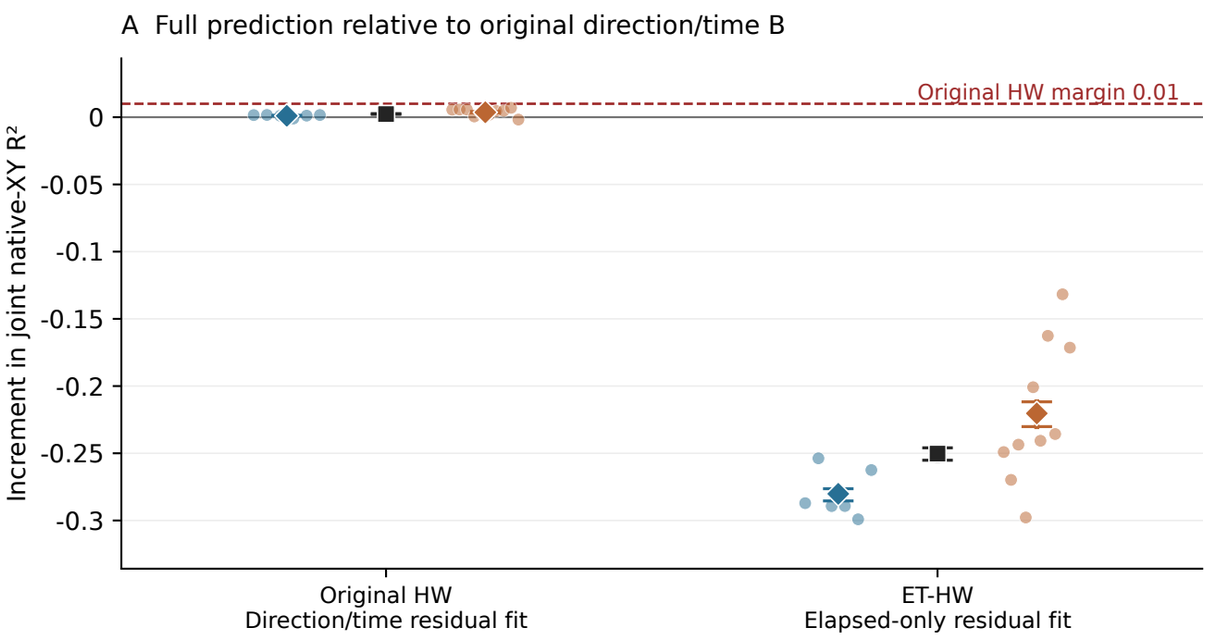
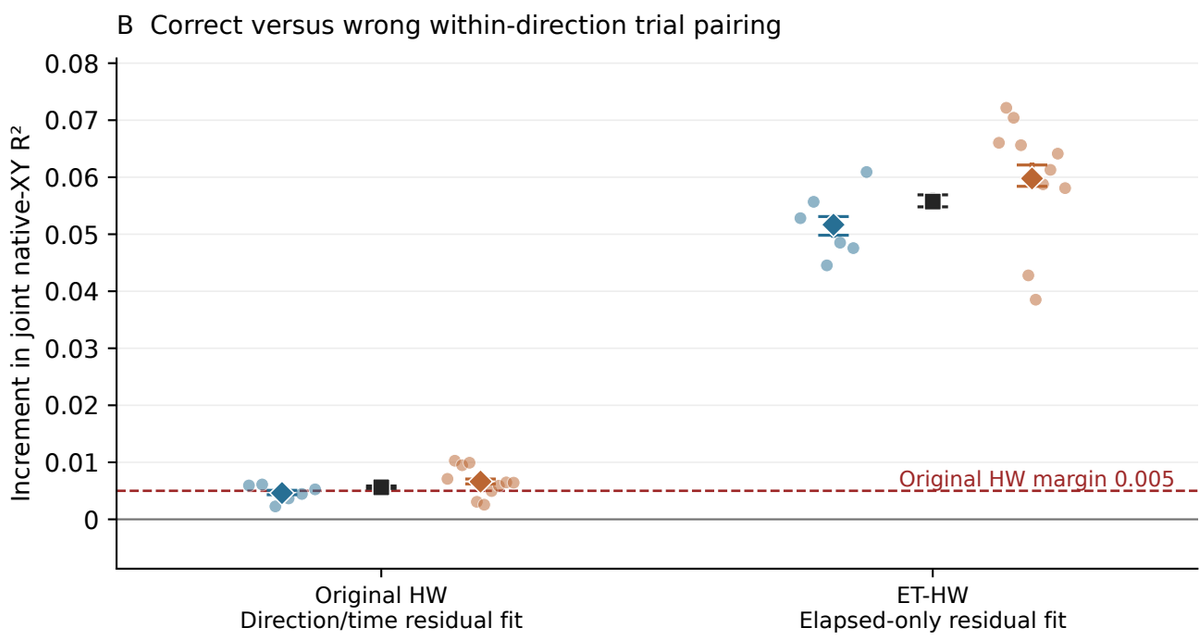
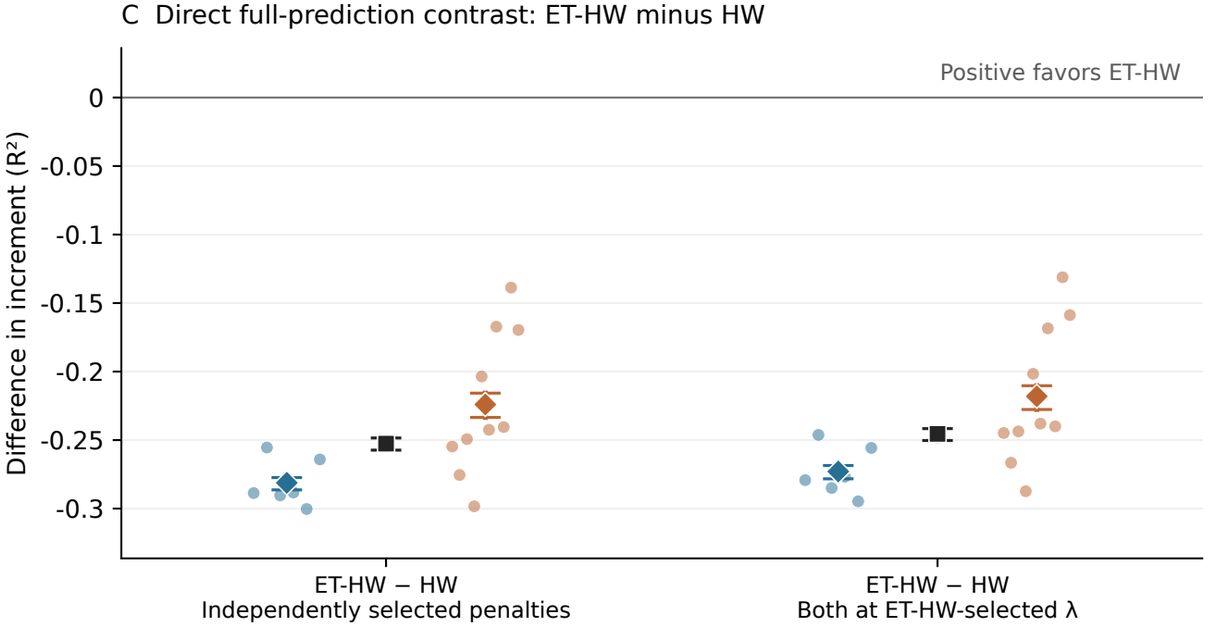
Elapsed-only fitting loses accuracy despite a larger pairing increment

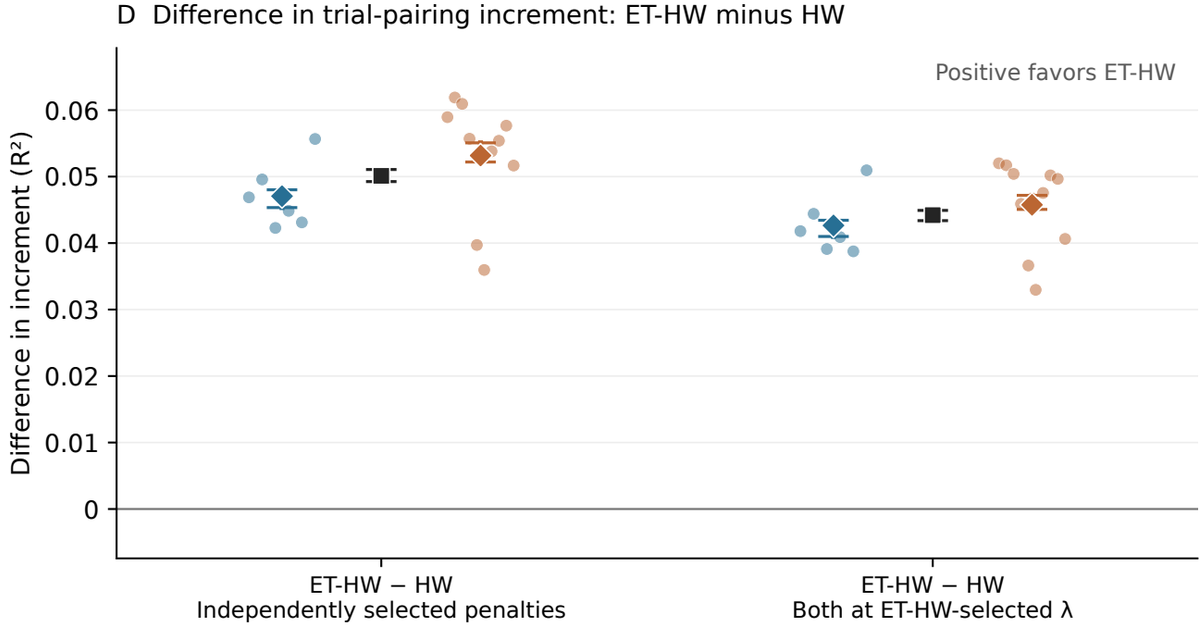
HW − T = (B − T) + (HW − B) = 1.222831 + 0.002341 = 1.225172 R²

The large HW-over-T gain includes the behavioral baseline. ET-HW gains 0.972583 over T, yet loses 0.250248 to B (all 16 sessions).









◆ Mihili mean ◆ Chewie mean ■ Equal-animal mean

Small dots: all 16 sessions. Bars: fixed-prediction session-omission ranges; not confidence intervals. Each panel has its own full signed scale.
B = original direction/time template + common residual intercept; T = equal-direction elapsed-only template + the same type of intercept.
ET-HW refits Y−T and adds T back; the HW feature design and weights stay fixed. Original HW predictions are preserved, with no refit.
Direct contrasts use full-prediction SSE and the same original-session denominator. Original HW selects λ=1; ET-HW selects λ=0.01 in every session.
The matched-λ comparison preserves the ridge operator, while the supplied baseline and fitting response differ. Stronger pairing does not rescue accuracy.
Exposed development data · 2 animals · ET-HW is nonpromotable · original HW primary margin still fails.
