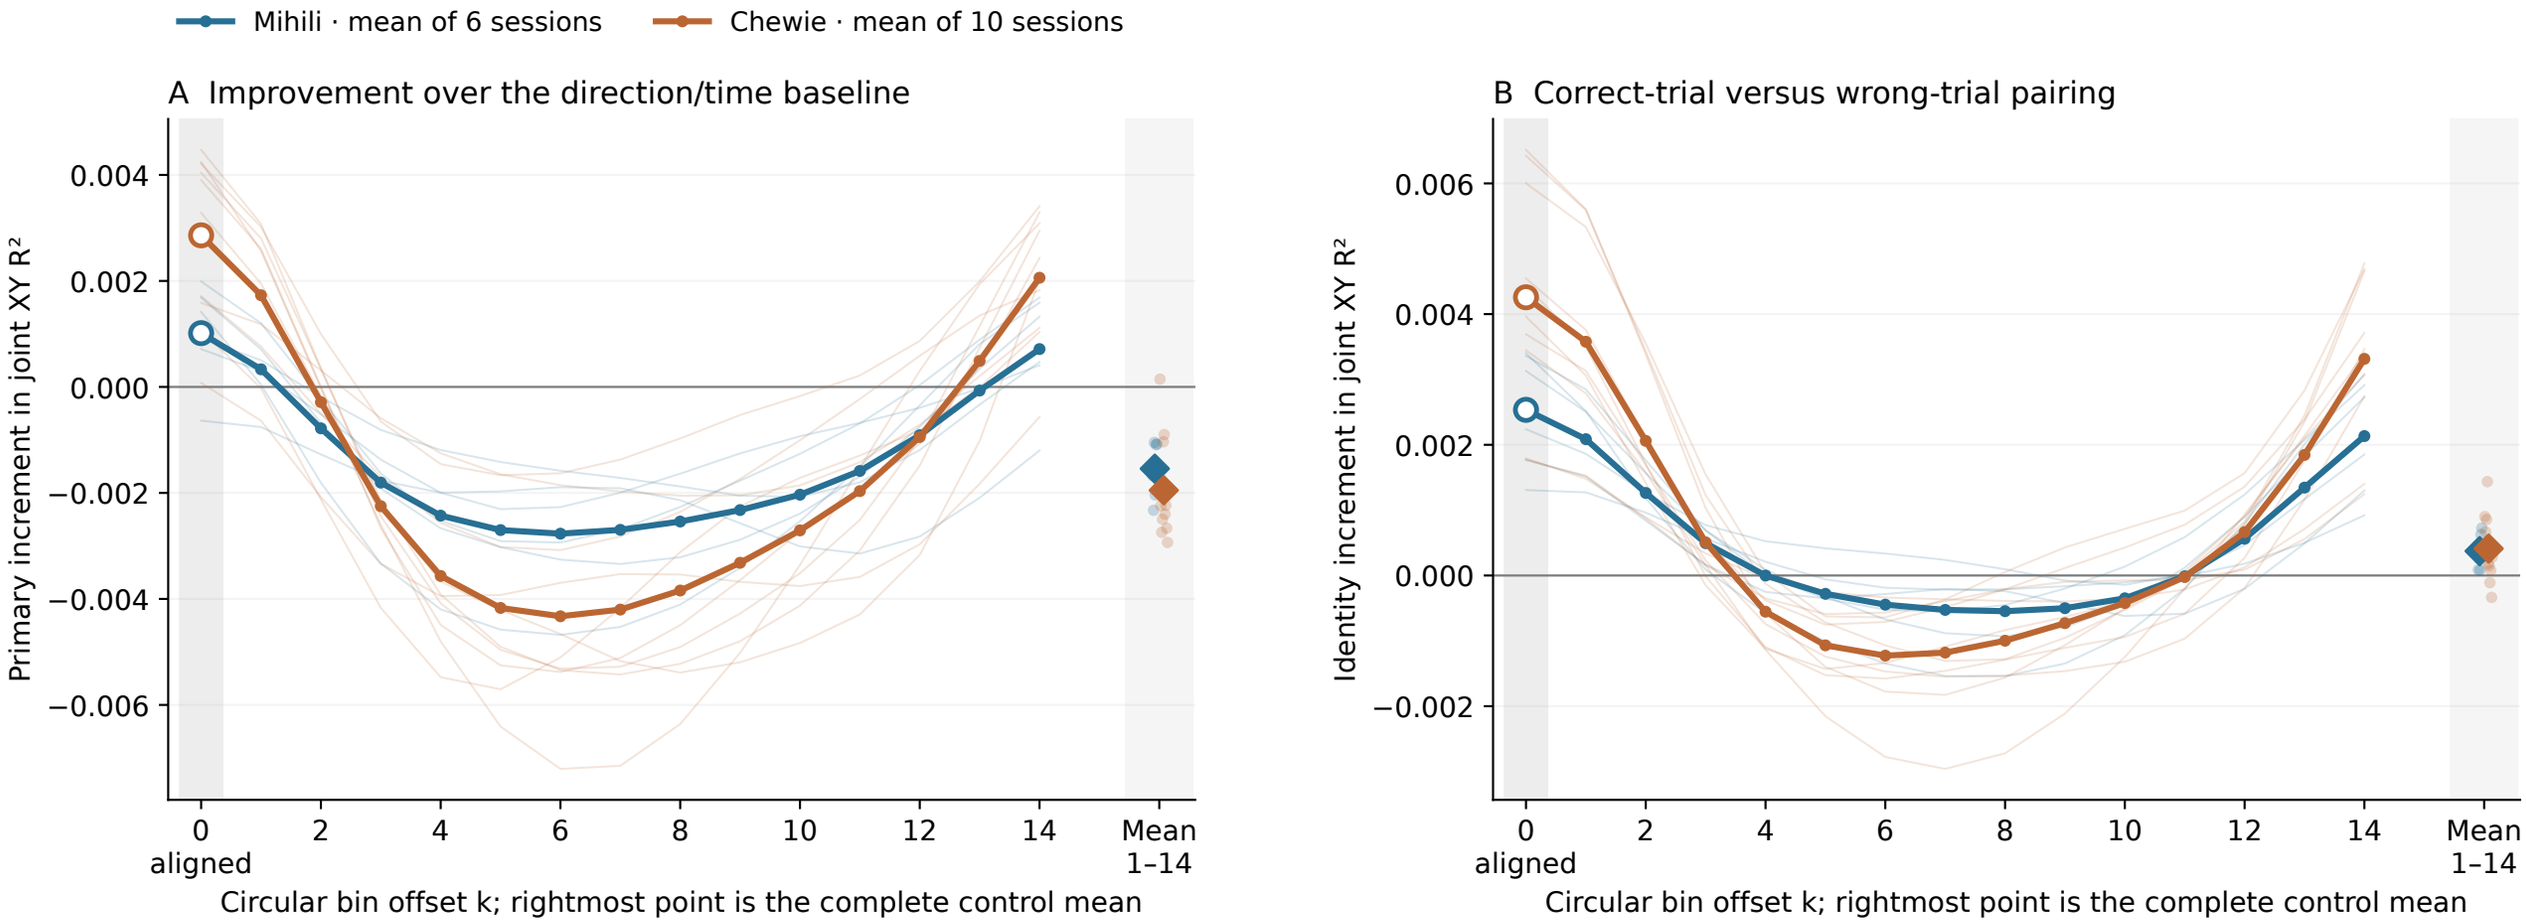
# EP05 · Temporal alignment of the fixed LMP decoder

Exposed development · 16 sessions, 2 animals · fixed anchor and penalty · $q_k(t) = (t + k) \bmod 15$



Faint traces and rightmost dots: all sessions. Solid curves: equal-session animal means. Hollow circles: aligned anchor; diamonds: control mean.

The control averages 14 nonzero-offset correct/wrong SSEs, not predictions. Offsets are the entire finite set, not Monte Carlo or biological replicates.

Circular wrapping can mix movement phases: k is not one physical lead/lag across every bin. No confidence intervals or promotion-threshold lines.

Source: completed primary_temporal_offset_attempt001/primary_temporal_offset.json. No new fits, source arrays, exclusions or offset selection.
