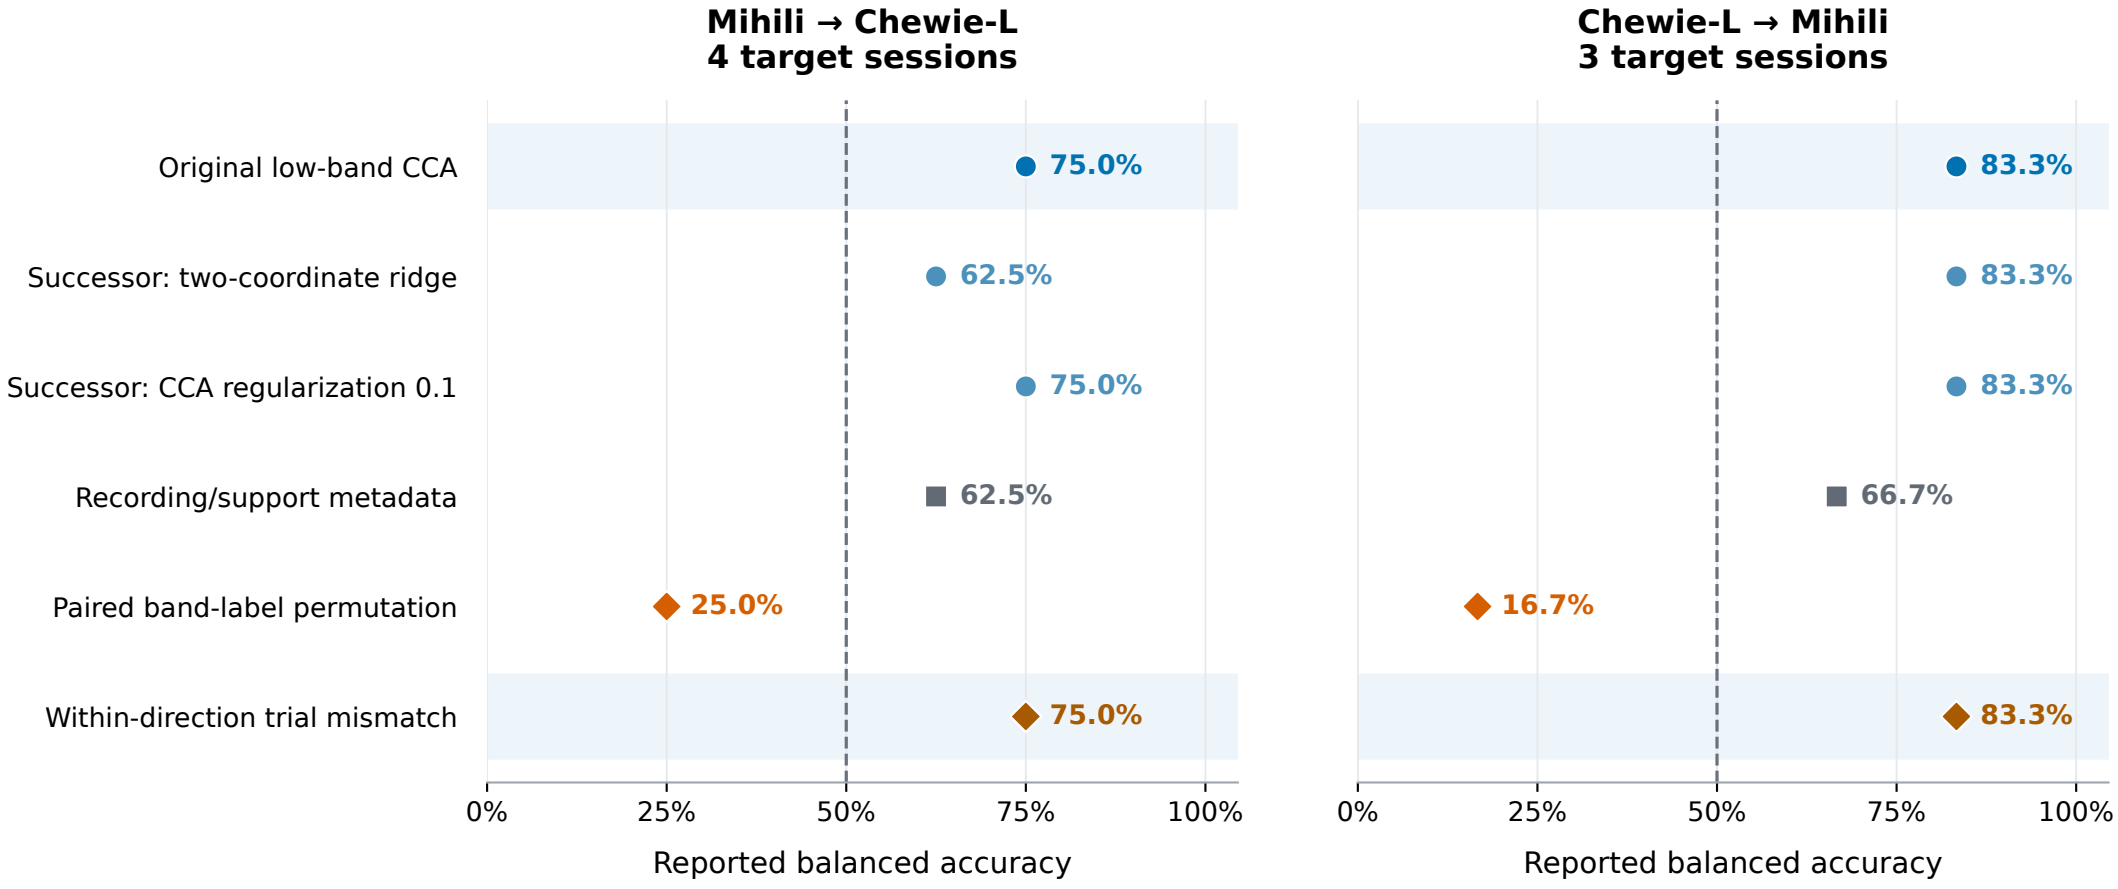
EP06: the three candidates fail signed-profile stability

Exploratory development | Seven sessions, two animals | Four reserved sessions remain closed

Neither successor improves the original; region-classification accuracy survives the trial mismatch.



Source-session influence: omit Mihili 2014-03-04 → Mihili-to-Chewie accuracy 50.0% (original 75.0%; the same four Chewie target sessions).

Dashed line: 50% chance reference, not a significance threshold. Points are existing estimates; no new intervals or tests.
One fixed band permutation and one fixed within-direction trial mismatch are sensitivities, not p-values.
Metadata scores below the original do not rule out recording confounds; unchanged accuracy does not establish unchanged recovery.
