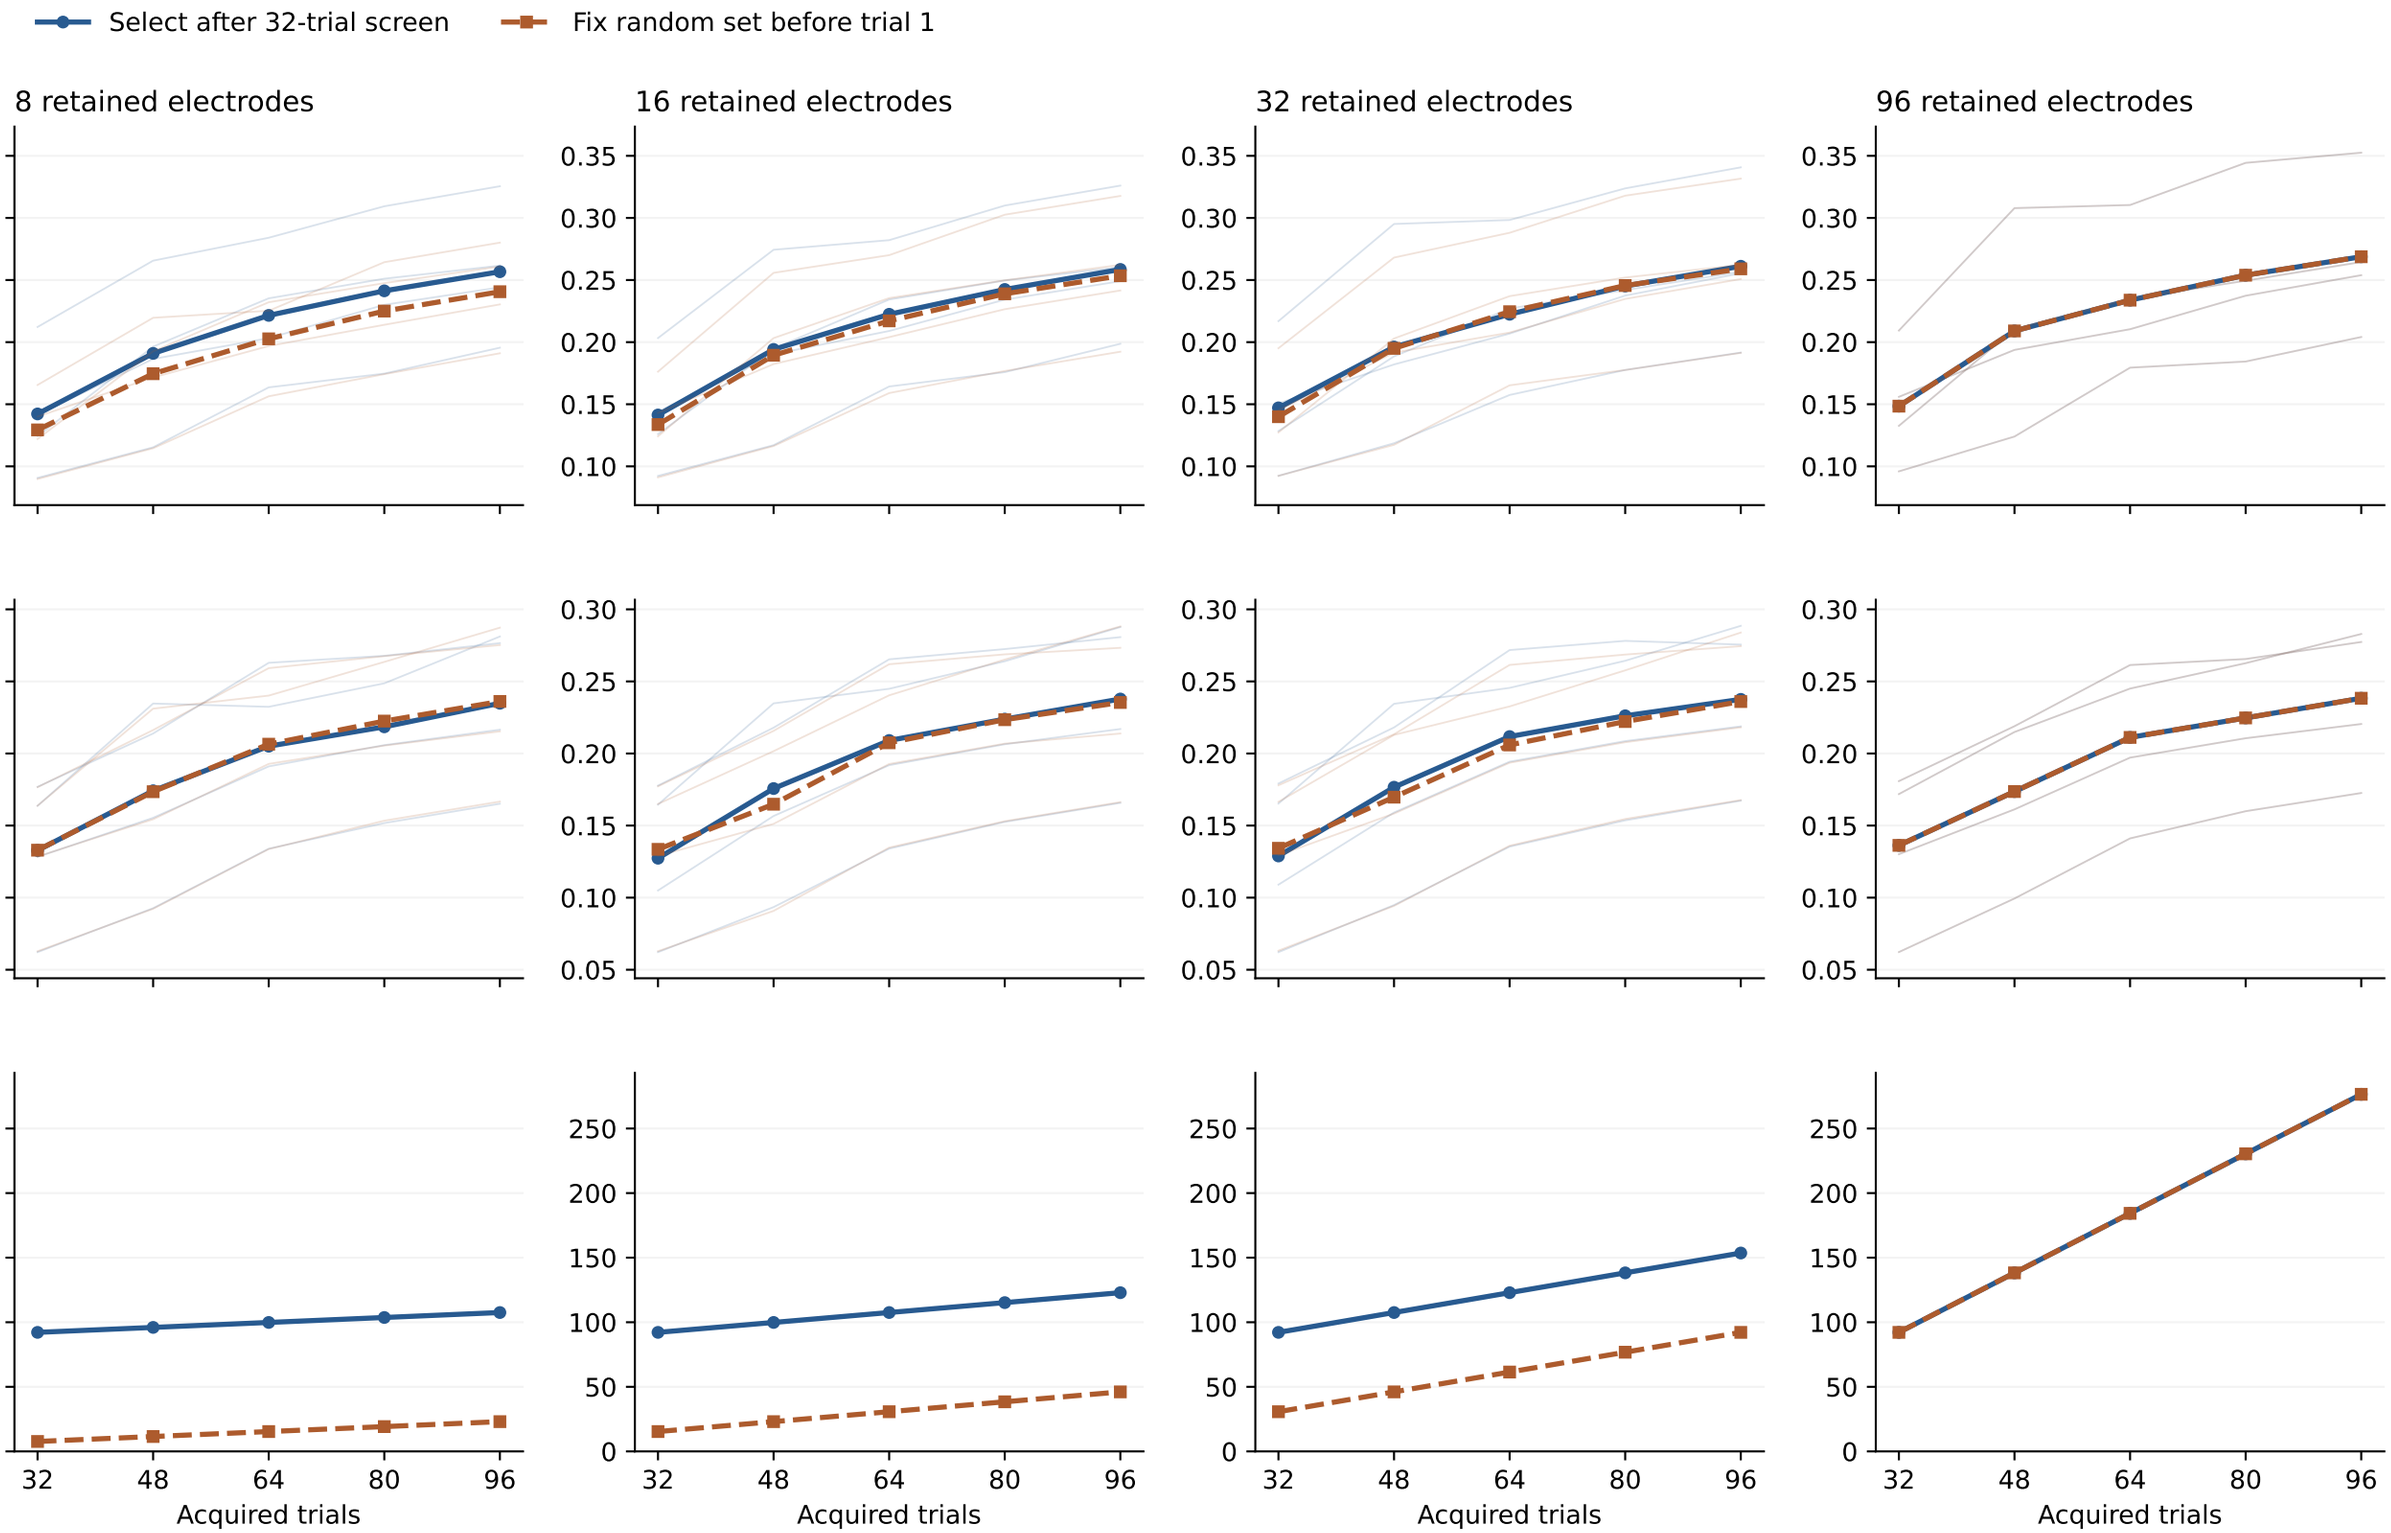
EP08 · Early electrode selection and its observation cost

Development only · fixed electrode sets after initialization · four held sessions remain closed



Bold: four-session animal means; faint: individual sessions. Random curves average the five scarce-set replicates. No confidence intervals.

Selection observes all 96 electrodes for 32 initial trials; random observes only its set. Each electrode-trial contributes 3 bands × 10 bins.

This is the separate 20-cell acquired-only protocol, not a continuation of the earlier 12-cell ranking. Initial observation costs are unequal.
